General Description

The AOZ13929DI-01 is a protection switch intended for applications that require reverse current protection. The input operating voltage range is between 3.4 V and 23 V, and both VIN and VOUT terminals are rated at 28 V Absolute Maximum. The power switch is capable for 20A surge current for 10 ms. AOZ13929DI-01 provides under-voltage lockout, startup short circuit protection, over-voltage and over-temperature protection. AOZ13929DI-01 also has integrated TVS diode for surge protection.

AOZ13929DI-01 is the ideal solution for multi-port Type-C PD current sinking application. The Ideal Diode True Reverse Current Blocking (IDTRCB) feature prevents VIN to rise due to reverse current flow from VOUT under all conditions.

An internal soft-start circuit controls inrush current due to highly capacitive loads and the slew rate can be adjusted using an external capacitor. The integrated back-to-back MOSFET offer industry’s lowest ON resistance and highest SOA to safely handle high current and a wide range of output capacitances on VOUT.

The AOZ13929DI-01 is available in a thermally enhanced 3.2 mm x 5.5 mm DFN-17L package which can operate over -40°C to +125°C junction temperature range.

Features

• 10A continuous sink current
• 20A peak current for 10 ms @ 2% duty cycle
• 13.5mΩ typical ON resistance
• 3.4 V to 23 V operating input voltage
• VIN and VOUT are rated 28 V Abs max
• Integrated TVS diode for surge protection
• Ideal Diode True Reverse Current Blocking (IDTRCB)
• Programmable Soft-Start
• VIN Under-Voltage Lockout (UVLO)
• VIN Over-Voltage Lockout (OVLO)
• Thermal Shutdown Protection
• Startup Short Circuit Protection
• IEC61000-4-2: ±30 kV (Air and Contact)
• IEC61000-4-5: 30 A (8/20 µs)
• Thermally Enhanced DFN3.2x5.5-17L package

Applications

• Thunderbolt/USB Type-C PD power switch
• Notebooks computer barrel jack
• Docking Stations / Dongles
• Power ORing applications

Detailed Description

The AOZ13929DI-01 is a high-side protection switch with programmable soft-start, over-voltage, and over-temperature protections. It is capable of operating from 3.4 V to 23 V. A TVS diode is integrated into the package for surge protection.

The internal power switch consists of back-to-back connected MOSFET. When the switch is enabled, the overall resistance between VIN and VOUT is only 13.5 mΩ, minimizing power loss and heat generation. The back-to-back configuration of MOSFET completely isolates VIN and VOUT when the switch is turned off, preventing leakage between the two pins.

Power Delivery Capability

During start-up, the voltage at VOUT linearly ramps up to the VIN voltage over a period of time set by the soft-start time. This ramp time is referred to as the soft-start time and is typically in milliseconds. Figure 9 illustrates the soft-start condition and power dissipation.

Power Dissipation = \( I_{SW} \times (V_{IN} - V_{OUT}) \)

To calculate the average power dissipation during the soft-start period: \( \frac{1}{2} \) of the input voltage should be used as the output voltage will ramp towards the input voltage, as shown in Figure 9.

For example, if the output capacitance \( C_{OUT} \) is 10 µF, the input voltage \( V_{IN} \) is 20 V, the soft-start time is 2 ms, and there is an additional 1 A of system current \( (I_{SYS}) \), then the average power being dissipated by the part is:

\[
I_{SW} = 10 \text{ } \mu\text{F} \times \frac{(20 \text{ } \text{V})}{(2 \text{ } \text{ms})} + 1 \text{ } \text{A} = 1.1 \text{ } \text{A}
\]

\[
\text{Average Power Dissipation} = 1.1 \text{ } \text{A} \times \frac{20 \text{ } \text{V}}{2} = 11 \text{ } \text{W}
\]

Referring to the SOA curve in Figure 10, the maximum power allowed for 2 ms is 120 W (6 A x 20 V or 12 A x 10 V). The AOZ13929DI-01 power switch is robust enough to drive a large output capacitance with load in reasonable soft-start time.

After soft-start is completed, the power switch is fully on, and it is at its lowest resistance under heavy load condition. The power switch acts as a resistor. Under this condition, the power dissipation is much lower than the soft-start period. However, as this is a continuous current, a low on-resistance is required to minimize power dissipation. Attention must be paid to board layout so that losses dissipated in the sinking switch are dissipated to the PCB and hence the ambient.
With a low on-resistance of 13.5 mΩ, the AOZ13929DI-01 provides the most efficient power delivery without much resistive power dissipation.

While Type C power delivery is limited to 20 V @ 5 A or 100 W, many high-end laptops require peak currents far in excess of the 5 A. While the thermal design current (TDC) for a CPU may be low, peak current (ICCmax in the case of Intel and EDP in the case of AMD) of many systems is often 2 x thermal design current. These events are typical of short duration (<2 ms) and low duty cycle, but they are important for system performance as a CPU/GPU capable of operating at several GHz can boost its compute power in those 2 ms peak current events. The AOZ13929DI-01 can handle such short, high current, transient pulses without any reliability degradation, thus enhancing the performance of high-end systems when plugged into the Type C adaptor.

The shorter the pulse and the lower the duty cycle, the higher the pulse current that the part can sustain. The part has enough time to dissipate the heat generated from the pulse current with longer off-time, as shown in Figure 11. For example, AOZ13929DI-01 can maintain 20 A for 10 ms with a duty cycle of 2%.

**Figure 11. AOZ13929DI-01 Sinking Switch Pulsed Current vs. Duration for a Given Duty Cycle**

### Enable

The active high EN pin is the ON/OFF control for the power switch. The device is enabled when the EN pin is high and not in UVLO state. The EN pin must be driven to a logic high (V_{EN,H}) or logic low (V_{EN,L}) state to guarantee operation. AOZ13929DI-01 draws about 32 μA supply current when it is disabled.

### Input Under-Voltage Lockout (UVLO)

The internal control circuit is powered from VIN. The under-voltage lockout (UVLO) circuit monitors the voltage at the input pin (VIN) and only allows the power switches to turn on when it is higher than 3.35 V (V_{UVLO}). If VIN is below 3 V, the device is in under-voltage lockout state.

### Over-Voltage Protection (OVP)

The voltages at VIN pin are constantly monitored once the device is enabled. In case the voltage exceeds the OVP threshold, over-voltage protection is activated:

1. If the power switch is on, it will be turned off after OVP debounce time (t_{OVP,DEB}) to isolate VOUT from VIN;
2. OVP will prevent power switch to be turned on if it is in off state;

In either case FLTB pin is pulled low to report the fault condition. The device can only be re-enabled by either toggling EN pin or cycling the input power supply.

### True Reverse Current Blocking

When the device is ON with no load or under light load conditions, it regulates VOUT to be 35 mV below VIN. As the load current is increasing or decreasing, the device adjusts the gate drive to maintain the 35 mV drop from VIN to VOUT. As the load current continues to increase the device increases the gate drive until the gate is fully turned on and VIN to VOUT drop is determined by IR drop through the MOSFET. If for any reason VOUT increases such that VIN to VOUT drop to less than 35 mV, the gate driver forces the switch to turn off.

The AOZ13929DI-01 also features a fast comparator that turns off the power switch upon detection of VOUT – VIN is higher than 50 mV (V_{TRCB}) after TRCB delay time (t_{TRCB,DEL}). When the AOZ13929DI-01 is first enabled or during each auto-restart, power switch will be kept off if VOUT is 50 mV higher than VIN.

### Thermal Shutdown Protection

When the die temperature reaches 140°C, the power switch is turned off. The device can only be re-enabled by either toggling EN pin or cycling the input power supply.

### Soft-Start Slew-Rate Control

When EN pin is asserted high, the slew rate control applies voltage on the gate of the power switch in a manner such that the output voltage is ramped up linearly until VOUT reaches VIN voltage level. The output ramps up time (t_{ON}) is programmable by an external soft-start capacitor (C_{SS}). The following formula provides the estimated 10% to 90% ramp up time.

$$t_{ON} = \left( \frac{VIN}{24} \right) \times \left( \frac{C_{SS}}{0.0023} - 100 \right)$$

where C_{SS} is in nF and t_{ON} is in µs.
System Startup
The device is enabled when \( EN \geq 1.4\, V \) and \( VIN \) is higher than UVLO threshold (\( V_{UVLO} \)). The device will check if any fault condition exists. If no fault exists, the power switch is turned on and \( VOUT \) is then ramped up after enable delay (\( t_{D\_ON} \)), controlled by the soft-start time (\( t_{ON} \)) until \( VOUT \) reaches \( VIN \) voltage level. Soft start time can be programmed externally through SS input with a capacitor \( C_{SS} \) to control in-rush current.

In-rush Current Limit and SCP at Start Up
AOZ13929DI-01 has the current limit and short circuit protection functions at start up. The current limit ramp increases linearly and reaches to a fixed current within 1.25 ms. With this fixed current limit ramp, the inrush current can be effectively clamped to reduce the initial current spikes. At initial startup, the internal power switch carries large voltage close to \( Vin \) and has large power loss. To ensure the internal FET working in Safe Operation Area (SOA), a fixed timer is set to shut down the power switch if the inrush current is clamped by current limit ramp for about 380 \( \mu s \) continuously. This timer will be reset once the inrush current drops below the current limit ramp. For short circuit event, the part will shut down after this 380 \( \mu s \) timer is finished. In case of large output capacitors, the soft start time needs to increase to avoid the large inrush current hit the current limit ramp for 380 \( \mu s \). The system will restart after 64 ms (\( t_{SCP\_RST} \)) blanking time. Both current limit and SCP shutdown are disabled after soft start time is finished.

Fault Protection
The AOZ13929DI-01 offers multiple protection against the following fault conditions: VIN Over Voltage Protection (OVP), True Reverse Current Blocking when \( VOUT > VIN \), and over temperature.

When the device is first enabled, the power switch is off and fault conditions are checked. If any of these conditions exist:

1. \( VIN \) is higher than the OVP threshold (\( V_{OVLO} \));
2. Die temperature is higher than thermal shutdown threshold (\( T_{SD} \));
3. \( VOUT \) is 50 mV (\( V_{FRCB} \)) higher than \( VIN \);

The power switch will not be turned on and FLTB pin will be pulled low for OVP and TSD conditions but not TRCB condition to indicate fault status of the device.

The power switch will be turned on once TRCB condition no longer exists. The device will continuously monitor these fault conditions. In addition, the short circuit condition is being monitored during the soft start.

Input Capacitor Selection
The input capacitor prevents large voltage transient from appearing at the input. It also provides the instantaneous current needed when the power switch turns on to charge output capacitors while limiting the input voltage drop. It is also to prevent high-frequency noise on the power line from passing through to the output. The input capacitor should be located as close to the VIN pin as possible. A 10 \( \mu F \) ceramic capacitor is recommended.

Output Capacitor Selection
The output capacitor has to supply enough current for a large peak current load that it may encounter during system transient. This bulk capacitance must be large enough to supply fast transient load in order to prevent the output from dropping.

Power Dissipation Calculation
The following equation can be used to estimate the power dissipation for normal load condition:

\[
\text{Power Dissipated} = R_{ON} \times (I_{OUT})^2
\]
Layout Guidelines

AOZ13929DI-01 is a protection switch designed to deliver high current. Layout is critical to remove the heat generated by this current. For the most efficient heat sinking, connect as much copper as possible to the exposed pad. The exposed pad is the common drain of the power switch which must be electrically isolated.

On the top layer expand the exposed pad island as much as possible for optimal thermal performance. The exposed pad copper plane must be electrically isolated. See example in Figure 12.

On the bottom layer, similar to the inner layers, create an isolated thermal island. Typically, there is more area available on the bottom area for a larger thermal pad. The top and bottom layers have better thermal performance than the inner layers because they are exposed to the atmosphere. See example in Figure 14.

There are two ways to create thermal islands on the inner layers as showed in Figure 13. The more layers that have these electrically isolated thermal heat sink islands the better the thermal performance will be. Connect all isolated thermal island (top, inner layers and bottom) together with as many VIAs as possible.
NOTE:
1. CONTROLLING DIMENSION IS MILLIMETER.
2. CONVERTED INCH DIMENSIONS ARE NOT NECESSARILY EXACT.

LIFE SUPPORT POLICY

ALPHA AND OMEGA SEMICONDUCTOR PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS.

As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.

2. A critical component in any component of a life support device, or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
